# Debugging iOS Applications with IDA Pro

## Table of Contents

## 1. Overview

This tutorial discusses optimal strategies for debugging native iOS applications with IDA Pro.

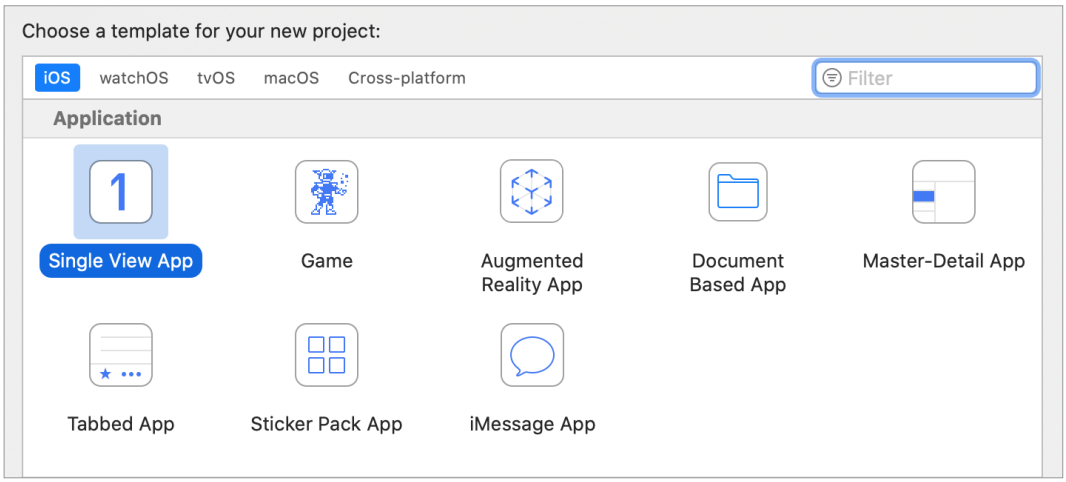
IDA Pro supports remote debugging on any iOS version since iOS 9 (including iPadOS). Debugging is generally device agnostic so it shouldn't matter which hardware you're using as long as it's running iOS. The debugger itself can be used on any desktop platform that IDA supports (Mac/Windows/Linux), although using the debugger on Mac makes more features available.

Note that IDA supports debugging on both jailbroken and non-jailbroken devices. Each environment provides its own unique challenges and advantages, and we will discuss both in detail in this writeup.

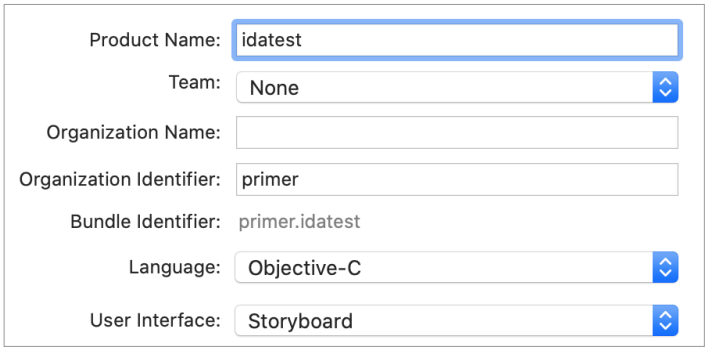
## 2. Getting Started

The quickest way to get started with iOS debugging is to use Xcode to install a sample app on your device, then switch to IDA to debug it.

In this example we'll be using an iPhone SE 2 with iOS 13.4 (non-jailbroken) while using IDA 7.5 SP1 on OSX 10.15 Catalina. Start by launching Xcode and use menu **File>New>Project…** to create a new project from one of the iOS templates, any of them will work:



After selecting a template, set the following project options:



Note the bundle identifier **primer.idatest**, it will be important later. For the **Team** option choose the team associated with your iOS Developer account, and click OK. Before building be sure to set the target device in the top left of the Xcode window:

Now launch the build in Xcode. If it succeeds then Xcode will install the app on your device automatically.

## 2.1. Preparing a Debugging Environment

Now that we have a test app installed on our device, let's prepare to debug it. First we must ensure that the iOS debugserver is installed on the device. Since our device is not jailbroken, this is not such a trivial task. By default iOS restricts all remote access to the device, and such operations are managed by special MacOS Frameworks.

Fortunately Hex-Rays provides a solution. Download the ios_deploy utility from our downloads page. This is a command-line support utility that can perform critical tasks on iOS devices without requiring a jailbreak. Try running it with the **listen** phase. If ios_deploy can detect your device it will print a message:

```
$ ios_deploy listen
Device connected:
- name:    iPhone SE 2
- model:   iPhone SE 2
- ios ver: 13.4
- build:   17E8255
- arch:    arm64e
- id:      XXXXXXXX-XXXXXXXXXXXXXXXX
```

Use the **mount** phase to install DeveloperDiskImage.dmg, which contains the debugserver:

```
$ export DEVELOPER=/Applications/Xcode.app/Contents/Developer
$ export DEVTOOLS=$DEVELOPER/Platforms/iPhoneOS.platform/DeviceSupport
$ ios_deploy mount -d $DEVTOOLS/13.4/DeveloperDiskImage.dmg
```

The device itself is now ready for debugging. Now let's switch to IDA and start configuring the debugger. Load the **idatest** binary in IDA, Xcode likely put it somewhere in its **DerivedData** directory:

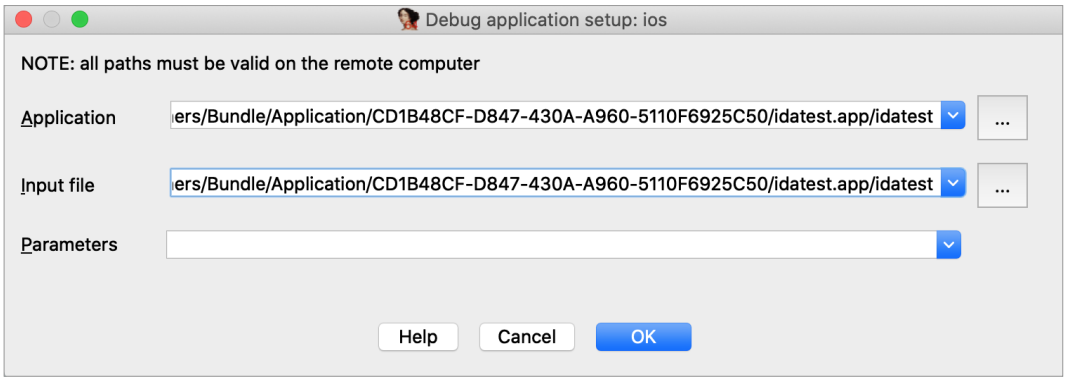
```
$ alias ida64="/Applications/IDA\ Pro\ 7.5\ sp1/ida64.app/Contents/MacOS/ida64"
$ export XCDATA=~/Library/Developer/Xcode/DerivedData
$ ida64 $XCDATA/idatest/Build/Products/Debug-iphoneos/idatest.app/idatest
```

Then go to menu **Debugger>Select debugger…** and select **Remote iOS Debugger**:

When debugging a binary remotely, IDA must know the full path to the executable on the target device. This is another task that iOS makes surprisingly difficult. Details of the filesystem are not advertised, so we must use ios_deploy to retrieve the executable path. Use the **path** phase with the app's bundle ID:

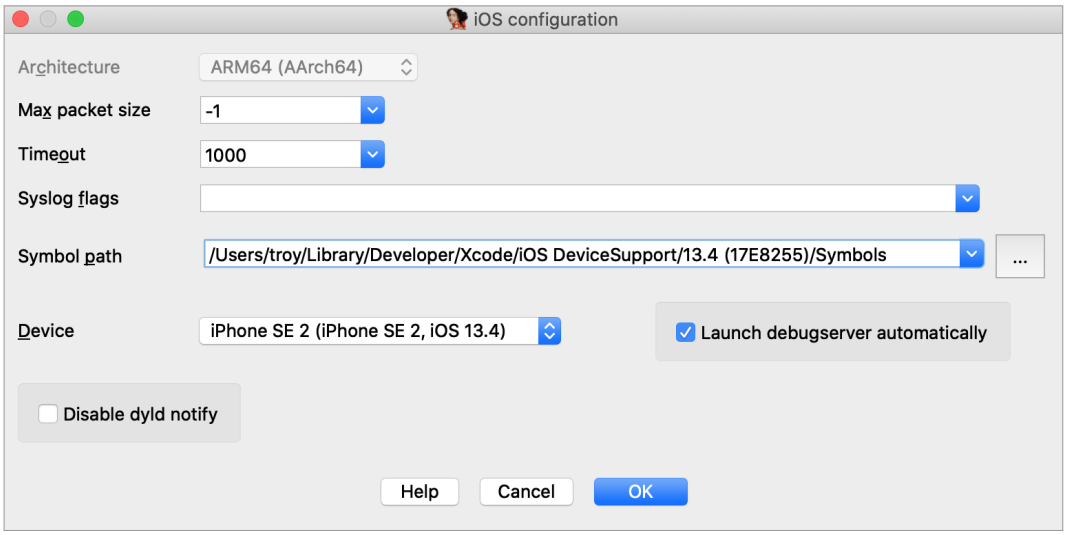
```
$ ios_deploy path -b primer.idatest
/private/var/containers/Bundle/Application/<UUID>/idatest.app/idatest
```

Use this path for the fields in **Debugger>Process options...**



**NOTE:** the path contains a hex string representing the application's 16-byte UUID. This id is regenerated every time you reinstall the app, so you must update the path in IDA whenever the app is updated on the device.

Now go to **Debugger>Debugger options>Set specific options...** and ensure the following fields are set:



Make special note of the **Symbol path** option. This directory contains symbol files extracted from your device. Both IDA and Xcode use these files to load symbol tables for system libraries during debugging (instead of reading the tables in process memory), which will dramatically speed up debugging.

Xcode likely already created this directory when it first connected to your device, but if not you can always use ios_deploy to create it yourself:

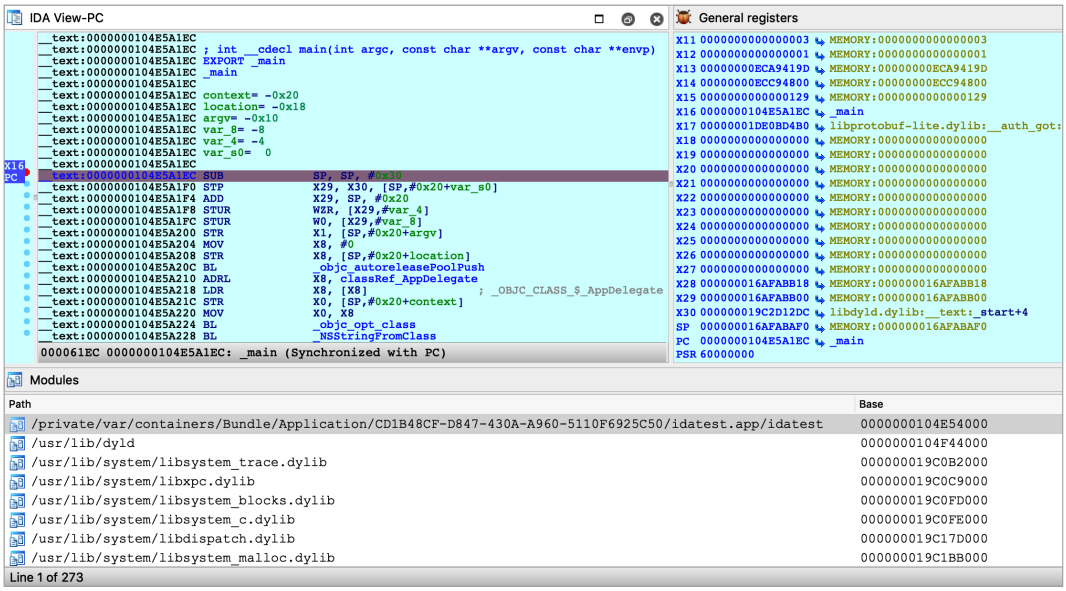
```
$ ios_deploy symbols
Downloading /usr/lib/dyld
Downloading 0.69 MB of 0.69 MB
Downloading /System/Library/Caches/com.apple.dyld/dyld_shared_cache_arm64e
Downloading 1648.38 MB of 1648.38 MB
Extracting symbol file: 1866/1866
/Users/troy/Library/Developer/Xcode/iOS DeviceSupport/13.4 (17E8255)/Symbols: done
```

Also ensure that the **Launch debugserver automatically** option is checked. This is required for non-jailbroken devices since we have no way to launch the server manually. This option instructs IDA to establish a connection to the debugserver itself via the MacOS Frameworks, which will happen automatically at debugging start.

Lastly, Xcode might have launched the test application after installing it. Use the **proclist** phase to retreive the app's pid and terminate it with the **kill** phase:

```
$ ios_deploy proclist -n idatest
32250
$ ios_deploy kill -p 32250
```

Finally we are ready to launch the debugger. Go to **main** in IDA's disassembly view, use **F2** to set a breakpoint, then **F9** to launch the process, and wait for the process to hit our breakpoint:



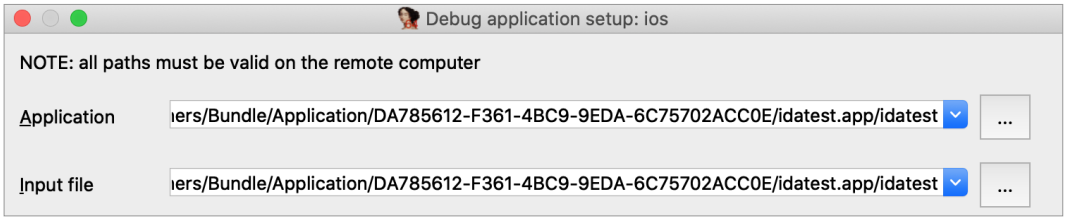
You are free to single step, inspect registers, and read/write memory just like any other IDA debugger.

# 3. Source Level Debugging

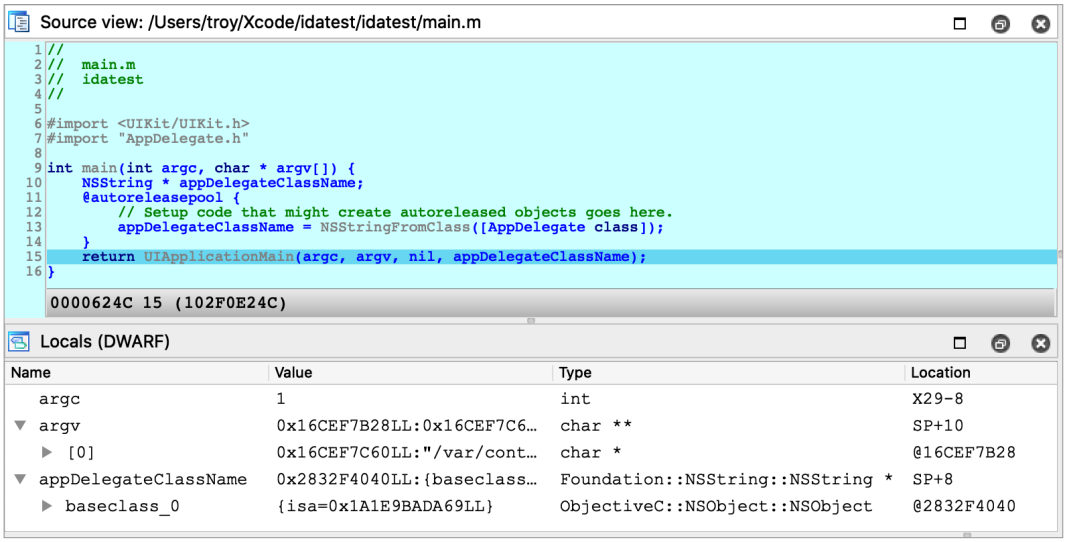
You can also use IDA to debug the source code of your iOS application. Let's rebuild the **idatest** application with the **DWARF with dSYM File** build setting:

Since the app is reinstalled, the executable path will change. We'll need to update the remote path in IDA:

```
$ ios_deploy path -b primer.idatest
```



Be sure to enable **Debugger>Use source-level debugging**, then launch the process. At runtime IDA will be able to load the DWARF source information:



Note that the debugserver does not provide DWARF information to IDA - instead IDA looks for dSYM bundles in the vicinity of the idb on your local filesystem. Thus if you want IDA to load DWARF info for a given module, both the module binary and its matching dSYM must be in the same directory as the idb, or in the idb's parent directory.

For example, in the case of the **idatest** build:

```
$ tree
.
├── idatest.app
│   ├── idatest
│   └── idatest.i64
└── idatest.app.dSYM
    └── Contents
        └── Resources
            └── DWARF
                └── idatest
```

IDA was able to find the **idatest** binary next to **idatest.i64**, as well as the dSYM bundle next to the parent app directory.

If IDA can't find DWARF info on your filesystem for whatever reason, try launching IDA with the command-line option **-z440010**, which will enable much more verbose logging related to source-level debugging:

```
Looking for Mach-O file "idatest.app/idatest.dSYM/Contents/Resources/DWARF/idatest"
File "idatest.app/idatest.dSYM/Contents/Resources/DWARF/idatest" exists? -> No.
Looking for Mach-O file "idatest.app.dSYM/Contents/Resources/DWARF/idatest"
File "idatest.app.dSYM/Contents/Resources/DWARF/idatest" exists? -> Yes.
Looking for cpu=16777228:0, uuid=7a09f307-7503-3c0d-a182-ab552c1bf182.
Candidate: cpu=16777228:0, uuid=7a09f307-7503-3c0d-a182-ab552c1bf182.
Found, with architecture #0
DWARF: Found DWARF file "idatest.app.dSYM/Contents/Resources/DWARF/idatest"
```

# 4. Debugging DYLD

IDA can also be used to debug binaries that are not user applications. For example, **dyld**.

The ability to debug dyld is a nice advantage because it allows us to observe critical changes in the latest versions of iOS (especially regarding the shared cache) before a jailbreak is even available. We document this functionality here in the hopes it will be useful to others as well.

In this example we'll be using IDA to discover how dyld uses ARMv8.3 Pointer Authentication to perform secure symbol bindings. Start by loading the dyld binary in IDA. It is usually found here:

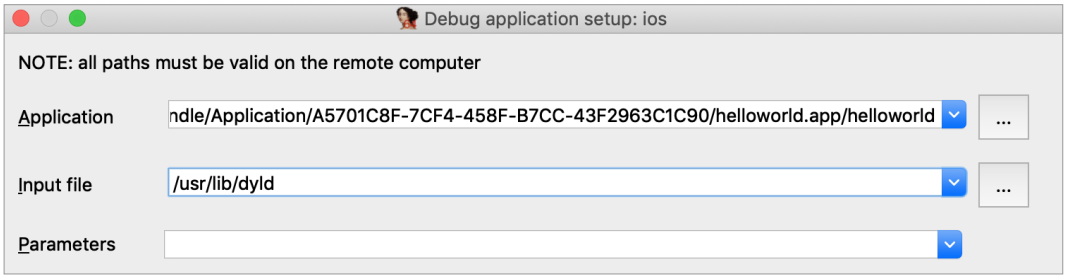
```
~/Library/Developer/Xcode/iOS DeviceSupport/13.4 (17E8255)/Symbols/usr/lib/dyld
```

The target application will be a trivial helloworld program:

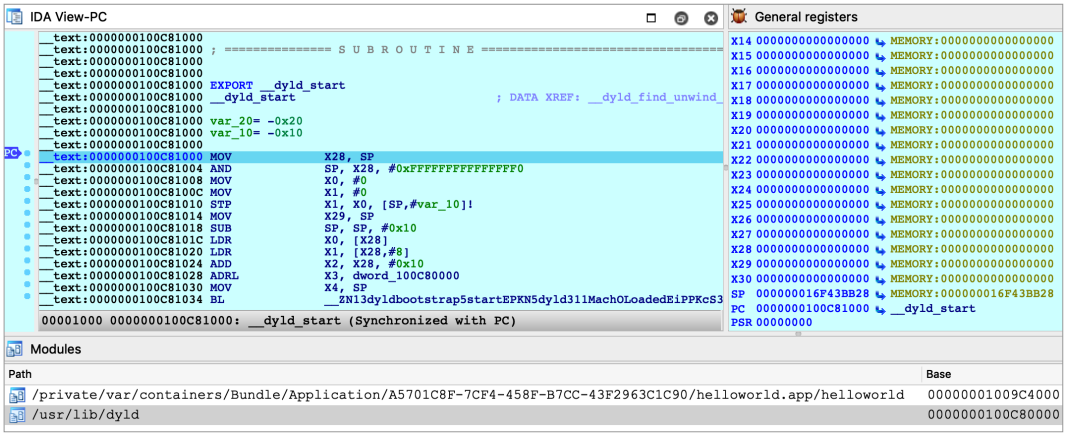
```
#include <stdio.h>

int main(void)
{
  puts("hello, world!\n");
  return 0;
}
```

Compile and install this app on your device, then set the following fields in **Debugger>Process options...**



Under **Debugger>Debugger options**, enable **Suspend on debugging start**. This will instruct IDA to suspend the process at dyld's entry point, before it has begun binding symbols. Now launch the process with **F9** - immediately the process will be suspended at **__dyld_start**:



Double-click on the **helloworld** module to bring up its symbol list and go to the **_main** function:

```
helloworld:__text:00000001009CBF74
helloworld:__text:00000001009CBF74 _main
helloworld:__text:00000001009CBF74
helloworld:__text:00000001009CBF74 var_s0=  0
helloworld:__text:00000001009CBF74
helloworld:__text:00000001009CBF74 PACIBSP
helloworld:__text:00000001009CBF78 STP             X29, X30, [SP,#-0x10+var_s0]!
helloworld:__text:00000001009CBF7C MOV             X29, SP
helloworld:__text:00000001009CBF80 ADR             X0, aHelloWorld         ; "hello, world!\n"
helloworld:__text:00000001009CBF84 NOP
helloworld:__text:00000001009CBF88 BL              sub_1009CBF98
helloworld:__text:00000001009CBF8C MOV             W0, #0
helloworld:__text:00000001009CBF90 LDP             X29, X30, [SP+var_s0],#0x10
helloworld:__text:00000001009CBF94 RETAB
helloworld:__text:00000001009CBF94 ; End of function _main
helloworld:__text:00000001009CBF94
```

Note that function **sub_1009CBF98** is the stub for **puts**:

```
helloworld:__auth_stubs:00000001009CBF98
helloworld:__auth_stubs:00000001009CBF98 sub_1009CBF98                   ; CODE XREF: _main+14↑p
helloworld:__auth_stubs:00000001009CBF98 ADRL            X17, off_1009CC000
helloworld:__auth_stubs:00000001009CBFA0 LDR             X16, [X17]      ; unk_C001000000000000
helloworld:__auth_stubs:00000001009CBFA4 BRAA            X16, X17        ; unk_C001000000000000
helloworld:__auth_stubs:00000001009CBFA4 ; End of function sub_1009CBF98
helloworld:__auth_stubs:00000001009CBFA4
```

The stub reads a value from **off_109CC000**, then performs a branch with pointer authentication. We can assume that at some point, dyld will fill **off_109CC000** with an authenticated pointer to **puts**. Let's use IDA to quickly track down this logic in dyld.

The iOS debugger supports watchpoints. Now would be a good time to use one:

```
ida_dbg.add_bpt(0x1009CC000, 8, BPT_WRITE)
```

Resume the process and wait for dyld to trigger our watchpoint:

```
100CA5DE4 MOV             X0, X19                 ; this
100CA5DE8 MOV             X1, X19                 ; void *
100CA5DEC BL              __ZNK5dyld311MachOLoaded25ChainedFixupPointerOnDisk6Arm64e11signPointerEPvy
100CA5DF0 MOV             X21, X0
100CA5DF4
100CA5DF4 loc_100CA5DF4                           ; CODE XREF: ____ZNK5dyld311MachOLoaded21fixupAllCha
100CA5DF4                                         ; ____ZNK5dyld311MachOLoaded21fixupAllChainedFixupsE
100CA5DF4 LDR             X0, [X20,#0x20]
100CA5DF8 CBZ             X0, loc_100CA5E10
100CA5DFC MOV             X8, X0
100CA5E00 LDR             X9, [X8,#0x10]!
100CA5E04 MOV             X1, X19
100CA5E08 MOV             X2, X21
100CA5E0C BLRAA           X9, X8
100CA5E10
100CA5E10 loc_100CA5E10                           ; CODE XREF: ____ZNK5dyld311MachOLoaded21fixupAllCha
100CA5E10 STR             X21, [X19]
100CA5E14 B               loc_100CA5E44
100CA5E18 ; ---------------------------------------------------------------------------

X17 0000000100CA5958
X18 0000000000000000
X19 00000001009CC000
X20 000000016F439F18
X21 BB457A81BA95ADD8
X22 00000001009C4000
X23 00000001009C4000
X24 00000001009CC000
X25 000000016F439F28
X26 000000016F43B0C0
X27 0000000100CF1610
X28 0000000000000000
X29 000000016F439E10
X30 A901E18100CA5E10
SP  000000016F439DE0
PC  000000100CA5E14
```

The instruction **STR X21 [X19]** triggered the watchpoint, and note the value in X21 (BB457A81BA95ADD8) which is the authenticated pointer to **puts**. Where did this value come from? We can see that X21 was previously set with **MOV X21, X0** after a call to this function:

```
dyld3::MachOLoaded::ChainedFixupPointerOnDisk::Arm64e::signPointer
```

It seems like we're on the right track. Also note that IDA was able to extract a nice stack trace despite dyld's heavy use of PAC instructions to authenticate return addresses on the stack:

```
Address    Module  Function
100CA5E14  dyld    ____ZNK5dyld311MachOLoaded21fixupAllChainedFixups_block_invoke
100CA5EEC  dyld    dyld3::MachOLoaded::walkChain
100CA5BF0  dyld    dyld3::MachOLoaded::forEachFixupInAllChains
100CA5B50  dyld    dyld3::MachOLoaded::fixupAllChainedFixups
100CA2210  dyld    ____ZN5dyld36Loader18applyFixupsToImage_block_invoke.68
100CB0218  dyld    dyld3::MachOAnalyzer::withChainStarts
100CA2004  dyld    ____ZN5dyld36Loader18applyFixupsToImage_block_invoke_3
100CB3314  dyld    dyld3::closure::Image::forEachFixup
100CA15EC  dyld    dyld3::Loader::applyFixupsToImage
100CA0A00  dyld    dyld3::Loader::mapAndFixupAllImages
100C88784  dyld    dyld::launchWithClosure
100C86BE0  dyld    dyld::_main
100C81228  dyld    dyldbootstrap::start
100C81034  dyld    __dyld_start
```

This leads us to the following logic in the dyld-733.6 source:

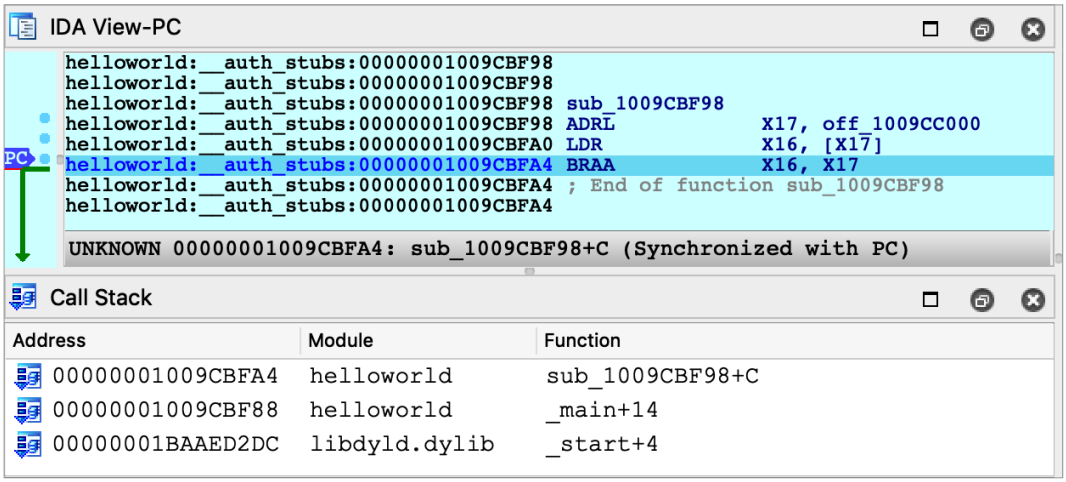
```
// authenticated bind
newValue = (void*)(bindTargets[fixupLoc->arm64e.bind.ordinal]);
if (newValue != 0)
    newValue = (void*)fixupLoc->arm64e.signPointer(fixupLoc, newValue);
```

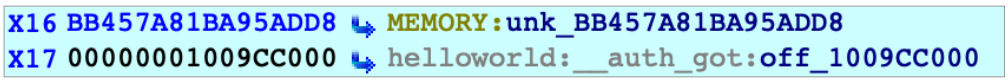
Here, **fixupLoc** (off_109CC00) and **newValue** (address of puts) are passed as the **loc** and **target** arguments for **Arm64e::signPointer**:

```
uint64_t discriminator = authBind.diversity;
if ( authBind.addrDiv )
    discriminator = __builtin_ptrauth_blend_discriminator(loc, discriminator);
switch ( authBind.key ) {
  case 0: // IA
    return __builtin_ptrauth_sign_unauthenticated(target, 0, discriminator);
  case 1: // IB
    return __builtin_ptrauth_sign_unauthenticated(target, 1, discriminator);
  case 2: // DA
    return __builtin_ptrauth_sign_unauthenticated(target, 2, discriminator);
  case 3: // DB
    return __builtin_ptrauth_sign_unauthenticated(target, 3, discriminator);
}
```

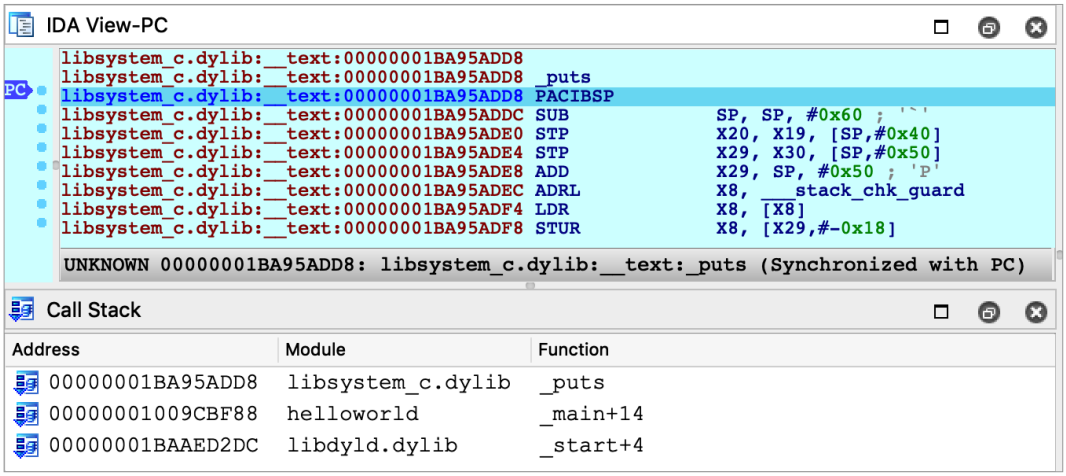
Thus, the pointer to **puts** is signed using its destination address in helloworld:__auth_got as salt for the signing operation. This is quite clever because the salt value is subject to ASLR and therefore cannot be guessed, but at this point the executable has already been loaded into memory — so it won't change by the time the pointer is verified in the stub.

To see this in action, use **F4** to run to the BRAA instruction in the stub and note the values of the operands:





The branch will use the operands to verify that the target address has not been modified after it was originally calculated by dyld. Since we haven't done anything malicious, one more single step should take us right to **puts**:



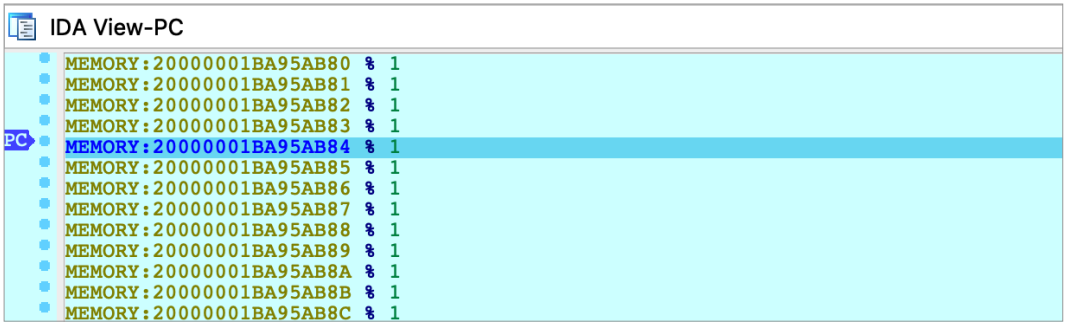
Just for fun, let's rewind the process back to the start of the stub:

```
IDC>PC = 0x1009CBF98
```

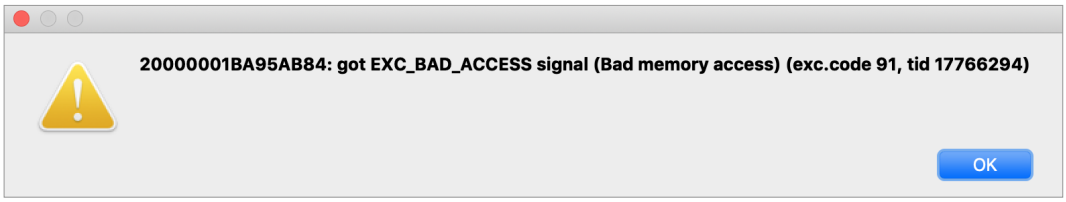
Then overwrite the authenticated pointer to **puts** with a raw pointer to **printf**:

```
ida_bytes.put_qword(0x1009CC000, ida_name.get_name_ea(BADADDR, "_printf"))
```

Now when we step through the stub, the BRAA instruction should detect that the authenticated pointer has been modified, and it will purposefully crash the application by setting PC to an invalid address:



Any attempt to resume execution will inevitably fail:



It seems we now have an understanding of secure symbol bindings in dyld. Fascinating!

# 5. Debugging the DYLD Shared Cache

This section discusses how to optimally debug system libraries in a dyld_shared_cache.

NOTE: full support for dyld_shared_cache debugging requires IDA 7.5 SP1

Debugging iOS system libraries is a challenge because the code is only available in the dyld cache. IDA allows you to load a library directly from the cache, but this has its own complications. A single module typically requires loading several other modules before the analysis becomes useful. Fortunately IDA is aware of these annoyances and allows you to debug such code with minimal effort.

To start, consider the following sample application that uses the CryptoTokenKit framework:

```
#import <CryptoTokenKit/CryptoTokenKit.h>

int main(void)
{
  TKTokenWatcher *watcher = [[TKTokenWatcher alloc] init];
  NSArray *tokens = [watcher tokenIDs];
  for ( int i = 0; i < [tokens count]; i++ )
    printf("%s\n", [[tokens objectAtIndex:i] UTF8String]);
  return 0;
}
```

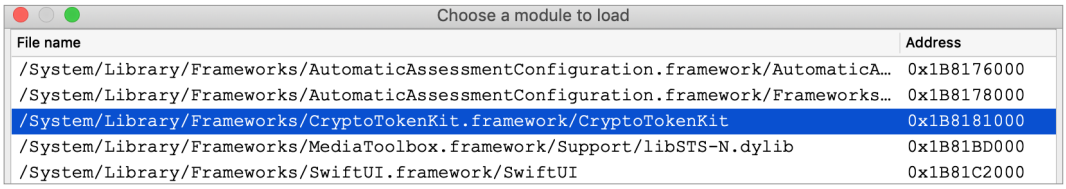
Assume this program has been compiled and installed on the device as **ctk.app**.

Instead of debugging the test application, let's try debugging the CryptoTokenKit framework itself - focusing specifically on the **-[TKTokenWatcher init]** method.

## 5.1. Initial Analysis

First we'll need access to the dyldcache that contains the CryptoTokenKit framework. The best way to obtain the cache is to extract it from the ipsw package for your device/iOS version. This ensures that you are working with the original untouched cache that was installed on your device.

When opening the cache in IDA, choose the load option **Apple DYLD cache for arm64e (single module)** and select the CryptoTokenKit module:



Wait for IDA to finish the initial analysis of CryptoTokenKit. Immediately we might notice that the analysis suffers because of references to unloaded code. Most notably many Objective-C methods are missing a prototype, which is unusual:

```
__text:00000001B81ADCF4
__text:00000001B81ADCF4 ; -[TKTokenWatcher endpoint]
__text:00000001B81ADCF4 __TKTokenWatcher_endpoint_              ; DATA XREF: CryptoTokenKit:__objc_const:
__text:00000001B81ADCF4
__text:00000001B81ADCF4 var_10          = -0x10
__text:00000001B81ADCF4 var_s0          =  0
__text:00000001B81ADCF4
__text:00000001B81ADCF4                 PACIBSP
__text:00000001B81ADCF8                 STP             X20, X19, [SP,#-0x10+var_10]!
__text:00000001B81ADCFC                 STP             X29, X30, [SP,#0x10+var_s0]
```

However this is expected. Modern dyld caches store all Objective-C class names and method selectors inside the libobjc module. Objective-C analysis is practically useless without these strings, so we must load the libobjc module to access them. Since a vast majority of modules depend on libobjc in such a way, it is a good idea to automate this in a script.

For a quick fix, save the following idapython code as **init.py**:

```
# improve functions with branches to unloaded code
idaapi.cvar.inf.af &= ~AF_ANORET

def dscu_load_module(module):
    node = idaapi.netnode()
    node.create("$ dscu")
    node.supset(2, module)
    load_and_run_plugin("dscu", 1)

# load libobjc, then analyze objc types
dscu_load_module("/usr/lib/libobjc.A.dylib")
load_and_run_plugin("objc", 1)
```

Then reopen the cache with:

```
$ ida64 -Sinit.py -Oobjc:+l dyld_shared_cache_arm64e
```

This will tell IDA to load libobjc immediately after the database is created, then perform the Objective-C analysis once all critical info is in the database. This should make the initial analysis acceptable in most cases. In the case of CryptoTokenKit, we see that the Objective-C prototypes are now correct:

```
__text:00000001B81ADCF4
__text:00000001B81ADCF4 ; NSXPCListenerEndpoint *__cdecl -[TKTokenWatcher endpoint](TKTokenWatcher *self, SEL)
__text:00000001B81ADCF4 __TKTokenWatcher_endpoint_              ; DATA XREF: CryptoTokenKit:__objc_const:000000
__text:00000001B81ADCF4
__text:00000001B81ADCF4 var_10          = -0x10
__text:00000001B81ADCF4 var_s0          =  0
__text:00000001B81ADCF4
__text:00000001B81ADCF4                 PACIBSP
__text:00000001B81ADCF8                 STP             X20, X19, [SP,#-0x10+var_10]!
__text:00000001B81ADCFC                 STP             X29, X30, [SP,#0x10+var_s0]
```

Now let's go to the **-[TKTokenWatcher init]** method invoked by the **ctk** application:

```
__text:00000001B81ADC54
__text:00000001B81ADC54 ; TKTokenWatcher *__cdecl -[TKTokenWatcher init](TKTokenWatcher *self, SEL)
__text:00000001B81ADC54 __TKTokenWatcher_init_                  ; DATA XREF: CryptoTokenKit:__objc_const:0000000
__text:00000001B81ADC54                 ADRP            X8, #sel_initWithClient_@PAGE ; "initWithClient:"
__text:00000001B81ADC58                 ADD             X1, X8, #sel_initWithClient_@PAGEOFF ; "initWithClient:"
__text:00000001B81ADC5C                 MOV             X2, #0
__text:00000001B81ADC60                 B               0x1B271C01C
__text:00000001B81ADC60 ; End of function -[TKTokenWatcher init]
__text:00000001B81ADC60
```

If we right-click on the unmapped address **0x1B271C01C**, IDA provides two options in the context menu:

Load ProVideo:__auth_stubs
Load ProVideo

In this case the better option is **Load ProVideo:__auth_stubs**, which loads only the stubs from the module and properly resolves the names:

```
__text:00000001B81ADC54
__text:00000001B81ADC54 ; TKTokenWatcher *__cdecl -[TKTokenWatcher init](TKTokenWatcher *self, SEL)
__text:00000001B81ADC54 __TKTokenWatcher_init_                  ; DATA XREF: CryptoTokenKit:__objc_const:0000000
__text:00000001B81ADC54                 ADRP            X8, #sel_initWithClient_@PAGE ; "initWithClient:"
__text:00000001B81ADC58                 ADD             X1, X8, #sel_initWithClient_@PAGEOFF ; "initWithClient:"
__text:00000001B81ADC5C                 MOV             X2, #0
__text:00000001B81ADC60                 B               j__objc_msgSend
__text:00000001B81ADC60 ; End of function -[TKTokenWatcher init]
__text:00000001B81ADC60
```

This is a common pattern in the latest arm64e dyldcaches, and it is quite convenient for us. Loading a handful of __auth_stubs sections is enough to resolve most of the calls in CryptoTokenKit, which gives us some nice analysis for **-[TKTokenWatcher init]** and its helper method:

Pseudocode-A

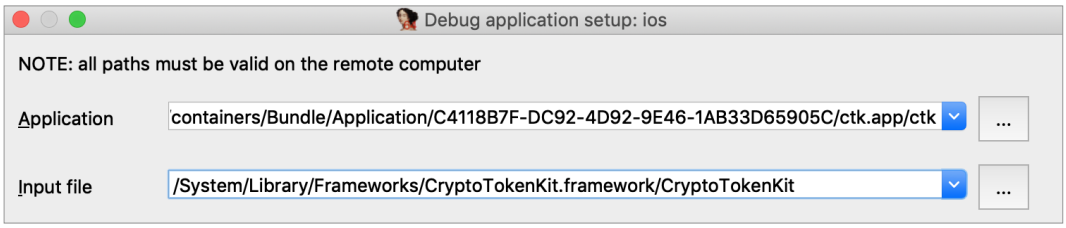
```
1 TKTokenWatcher *__cdecl -[TKTokenWatcher init](TKTokenWatcher *self, SEL a2)
2 {
3   return -[TKTokenWatcher initWithClient:](self, "initWithClient:", 0LL);
4 }
```

Pseudocode-A

```
1  TKTokenWatcher *__cdecl -[TKTokenWatcher initWithClient:](TKTokenWatcher *self, SEL a2, id client)
2  {
3    // [COLLAPSED LOCAL DECLARATIONS. PRESS KEYPAD CTRL-"+" TO EXPAND]
4
5    client = j__objc_retain(client);
6    super.receiver = self;
7    super.super_class = &OBJC_CLASS___TKTokenWatcher;
8    self = -[NSObject init](&super, "init");
9    if ( self )
10   {
11     if ( client )
12     {
13       v6 = 0;
14       _client = client;
15     }
16     else
17     {
18       _client = j__objc_alloc_0(&OBJC_CLASS___TKClientToken);
19       _client = -[TKClientToken initWithTokenID:](_client, "initWithTokenID:", &stru_1CA3DE288);
20       v6 = 1;
21     }
22     objc_storeStrong(&self->_client, _client);
23     if ( v6 )
24       j__objc_release(_client);
```

## 5.2. Debugger Configuration

Now that the static analysis is on par with a typical iOS binary, let's combine it with dynamic analysis. We can debug this database by setting the following options in **Debugger>Process options**:



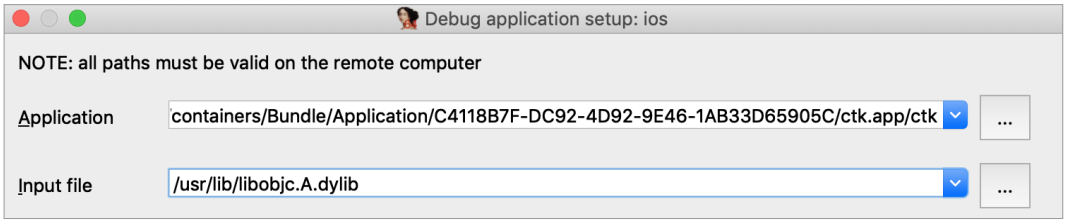
Here we set the **Input file** field to the full path of the CryptoTokenKit module. This allows IDA to easily detect the dyldcache slide at runtime. When CryptoTokenKit is loaded into the process, IDA will compare its runtime load address to the imagebase in the current idb, then rebase the database accordingly.

By default the imagebase in the idb corresponds to the first module that was loaded:

```
IDC>msg("%a", get_imagebase())
CryptoTokenKit:HEADER:00000001B8181000
```

Thus, it is easiest to set **Input file** to the module corresponding to the default imagebase.

Note however that we could also use this configuration:

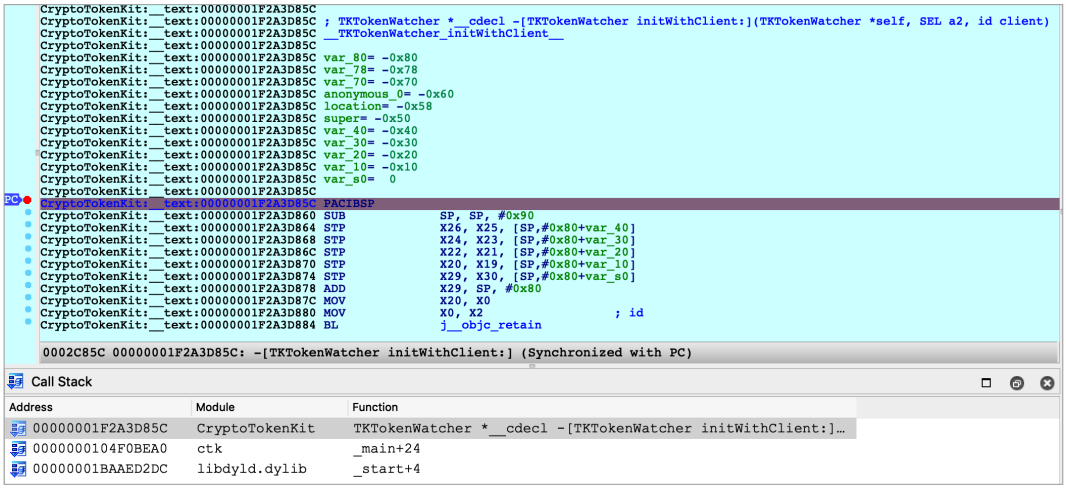


Provided that we update the imagebase in the idb to the base of the libobjc module:

```
ida_nalt.set_imagebase(ida_segment.get_segm_by_name("libobjc.A:HEADER").start_ea)
```

This will result in the same dyld slide and should work just as well, because the the imagebase and the **Input file** field both correspond to the same module. This is something to keep in mind when debugging dyldcache idbs that contain multiple libraries.

Now let's try launching the debugger. Set a breakpoint at **-[TKTokenWatcher initWithClient:]**, use **F9** to launch the process, then wait for our breakpoint to be hit:



IDA was able to map our database (including CryptoTokenKit, libobjc, and the satellite __auth_stubs sections) into process memory. We can single step, resume, inspect registers, and perform any other operation that is typical of an IDA debugging session.

## 5.3. Further Analysis

Note that after terminating the debugging session you can continue to load new modules from the cache. If a dyld slide has been applied to the database, new modules will be correctly loaded into the rebased address space. This did not work in previous versions of IDA.

For example, after a debugging session we might notice some more unresolved calls:

```
CryptoTokenKit:__text:00000001F2A3DD64  MOV   X19, X0
CryptoTokenKit:__text:00000001F2A3DD68  LDR   W0, [X0,#8]
CryptoTokenKit:__text:00000001F2A3DD6C  BL    0x1EFF0CB20
CryptoTokenKit:__text:00000001F2A3DD70  LDR   X0, [X19,#0x10] ; id
CryptoTokenKit:__text:00000001F2A3DD74  ADRP  X8, #sel_invalidate@PAGE ; "invalidate"
```

IDA is aware that the address space has shifted, and it will load the new code at the correct address:

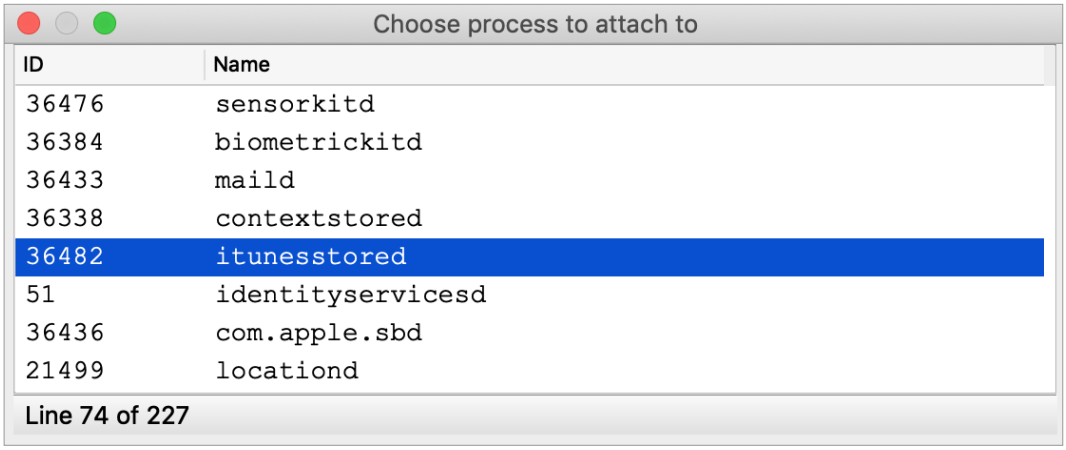
```
CryptoTokenKit:__text:00000001F2A3DD64  MOV   X19, X0
CryptoTokenKit:__text:00000001F2A3DD68  LDR   W0, [X0,#8]
CryptoTokenKit:__text:00000001F2A3DD6C  BL    j__notify_cancel_0
CryptoTokenKit:__text:00000001F2A3DD70  LDR   X0, [X19,#0x10] ; id
CryptoTokenKit:__text:00000001F2A3DD74  ADRP  X8, #sel_invalidate@PAGE ; "invalidate"
```

You are free to load new modules and relaunch debugging sessions indefinitely.

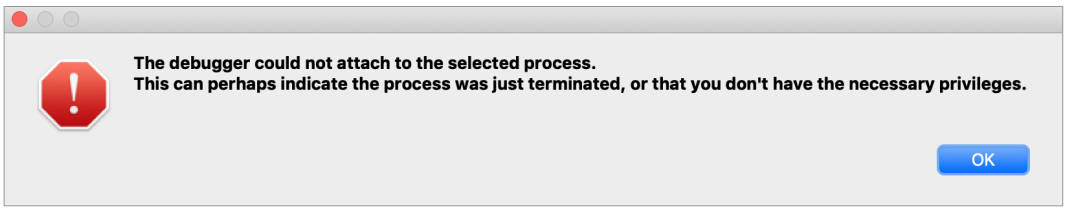
# 6. Debugging System Applications

The previous examples used custom applications to demonstrate IDA's debugging capabilities. In this case IDA can utilize the debugserver included in Apple's iOS developer tools, but there are situations in which this server is not sufficient for our needs.

The debugserver will refuse to debug any application that we didn't build ourselves. To demonstrate this, try launching IDA with an empty database and use **Debugger>Attach>Remote iOS Debugger** to attach to one of the system daemons:



You will likely get this error message:



It is possible to install a custom version of the debugserver that can debug system processes, but this requires a jailbroken device. We document the necessary steps and IDA configuration here. The device used in this example is an iPhone 8 with iOS 13.2.2, jailbroken with checkra1n 0.10.1.

## 6.1. Patching the debugserver

First we must obtain a copy of the debugserver binary from the DeveloperDiskImage.dmg:

```
$ export DEVELOPER=/Applications/Xcode.app/Contents/Developer
$ export DEVTOOLS=$DEVELOPER/Platforms/iPhoneOS.platform/DeviceSupport
$ hdiutil mount $DEVTOOLS/13.2/DeveloperDiskImage.dmg
$ cp /Volumes/DeveloperDiskImage/usr/bin/debugserver .
```

Now save the following xml as **entitlements.plist**:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/ PropertyList-
1.0.dtd">
<plist version="1.0">
<dict>
    <key>task_for_pid-allow</key> <true/>
    <key>get-task-allow</key> <true/>
    <key>platform-application</key> <true/>
    <key>com.apple.springboard.debugapplications</key> <true/>
    <key>run-unsigned-code</key> <true/>
    <key>com.apple.system-task-ports</key> <true/>
</dict>
</plist>
```

Then use ldid to codesign the server:

```
$ ldid -Sentitlements.plist debugserver
```

This will grant the debugserver permission to debug any application, including system apps. Now we can copy the server to the device and run it:

```
$ scp debugserver root@iphone-8:/usr/bin/
$ ssh root@iphone-8
iPhone-8:~ root# /usr/bin/debugserver 192.168.1.7:1234
debugserver-@(#)PROGRAM:LLDB  PROJECT:lldb-900.3.98 for arm64.
Listening to port 1234 for a connection from 192.168.1.7...
```

Note that we specified **192.168.1.7** which is the IP of the host machine used in this example. Be sure to replace this with the IP of your host so that the server will accept incoming connections from IDA.

## 6.2. IDA Configuration

To enable debugging with the patched debugserver, set the following options in dbg_ios.cfg:

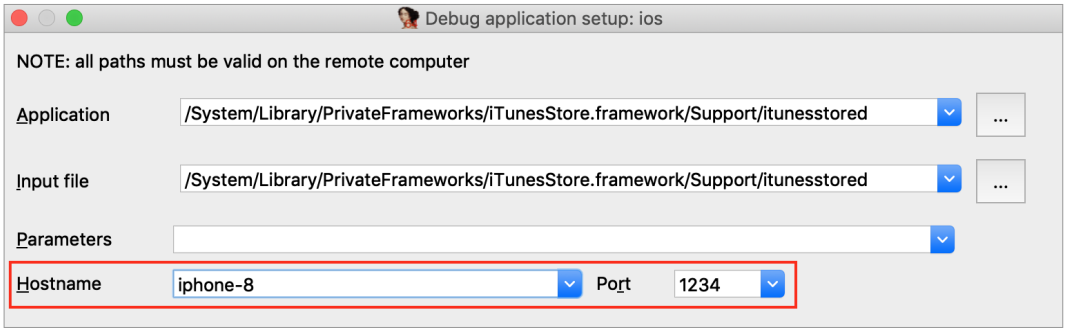
```
// don't launch the debugserver. we did it manually
AUTOLAUNCH = NO
// your device's UUID. this is used when fetching the remote process list
DEVICE_ID = "";
// debugging symbols extracted by Xcode
SYMBOL_PATH = "~/Library/Developer/Xcode/iOS DeviceSupport/13.2.2 (17B102)/Symbols";
```

We're now ready to open a binary in IDA and debug it. Copy the **itunesstored** binary from your device, it is typically found here:

```
/System/Library/PrivateFrameworks/iTunesStore.framework/Support/itunesstored
```

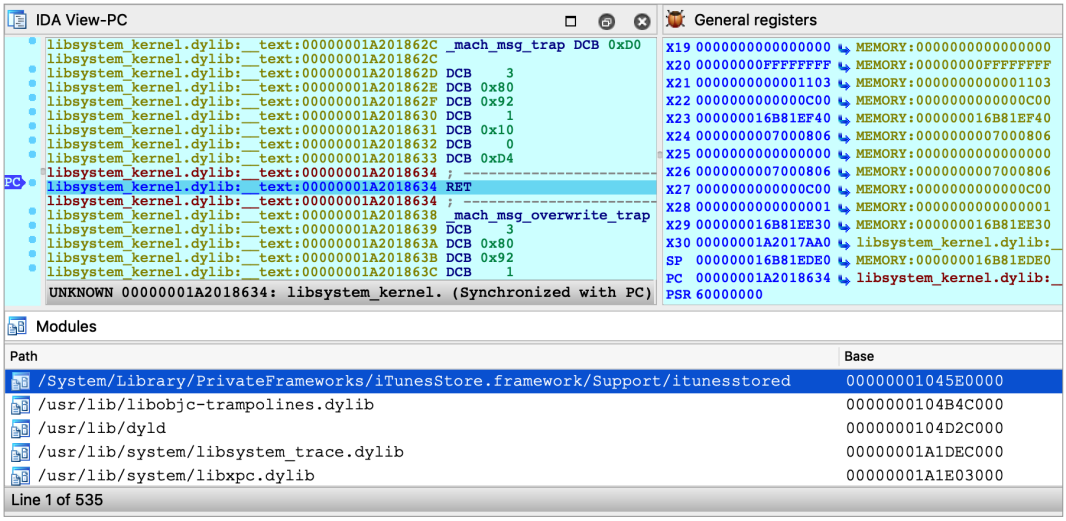
After loading the binary use **Debugger>Select debugger** and choose **Remote iOS Debugger**, then

under **Debugger>Process options** set the following fields:

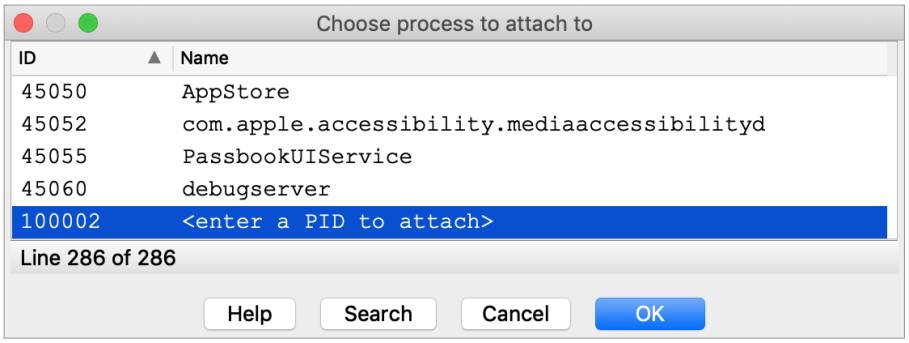


Since we set **AUTOLAUNCH = NO**, IDA now provides the **Hostname** and **Port** fields so we can specify how to connect to our patched debugserver instance.

Now use **Debugger>Attach to process** and choose **itunesstored** from the process list. Since we have modified the debugserver it should agree to debug the target process, allowing IDA to create a typically robust debugging environment:

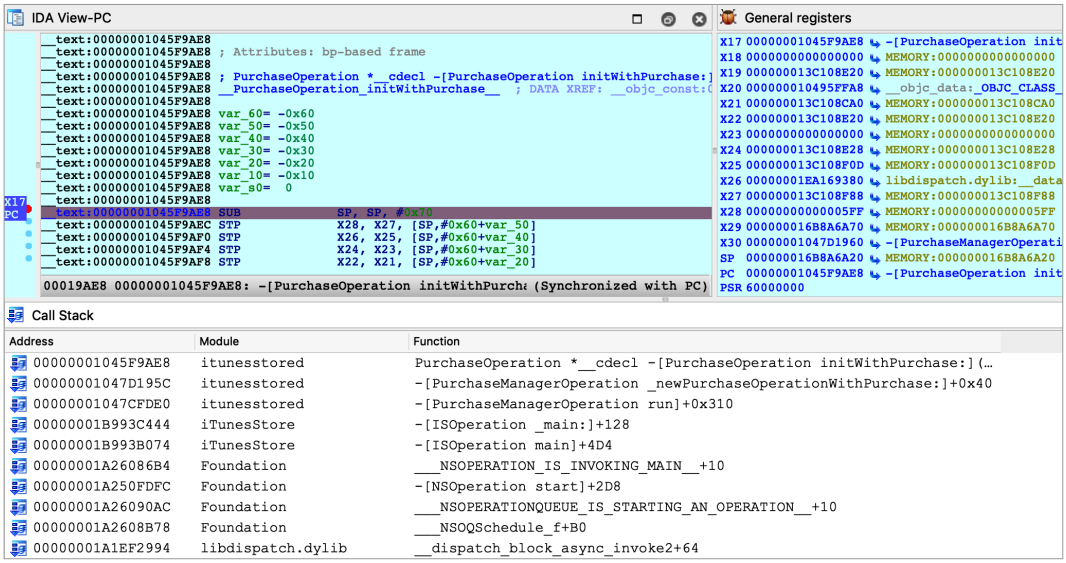


Note that although we're not using the debugserver from DeveloperDiskImage.dmg, IDA still depends on other developer tools to query the process list. We discuss how to install the DeveloperDiskImage in the Getting Started section above, but for a quick workaround you can always just specify the PID manually:

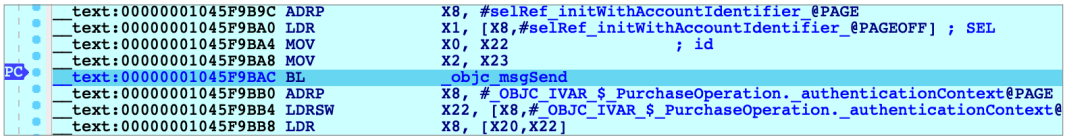


Now that we've successfully attached to a system process, let's do something interesting with it. Consider the method **-[PurchaseOperation initWithPurchase:]**. This logic seems to be invoked when a transaction is performed in the AppStore. Set a breakpoint at this method, then open the AppStore on your device and try downloading an app (it can be any app, even a free one).

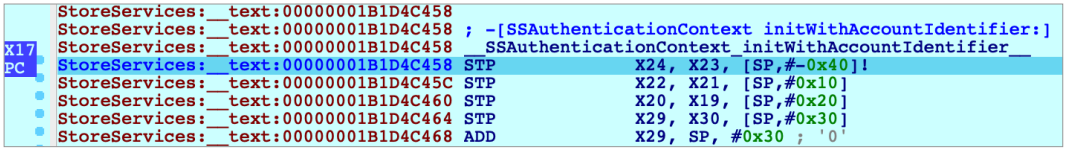
Immediately our breakpoint is hit, and we can start unwinding the logic that brought us here:



Stepping through this function, we see many Objective-C method call sites:



Instead of using **F7** to step into the _objc_msgSend function, we can use shortcut **Shift-O** to take us directly to the Objective-C method that is being invoked:



We discuss the **Shift-O** action in detail in our mac debugger tutorial, but it is worth demonstrating that this action works just as well in arm64/iOS environments.

It seems that we're well on our way to reverse-engineering transactions in the AppStore. The remaining work is left as an exercise for the reader :)

## 6.3. Conclusion

Hopefully by now we've shown that IDA's iOS Debugger is quite versatile. It can play by Apple's rules when debugging on a non-jailbroken device, and it can also be configured to use an enhanced debugserver when a jailbreak is available.

Also keep in mind that all previous examples in this writeup should work equally well with the patched debugserver. We encourage you to go back and try them.

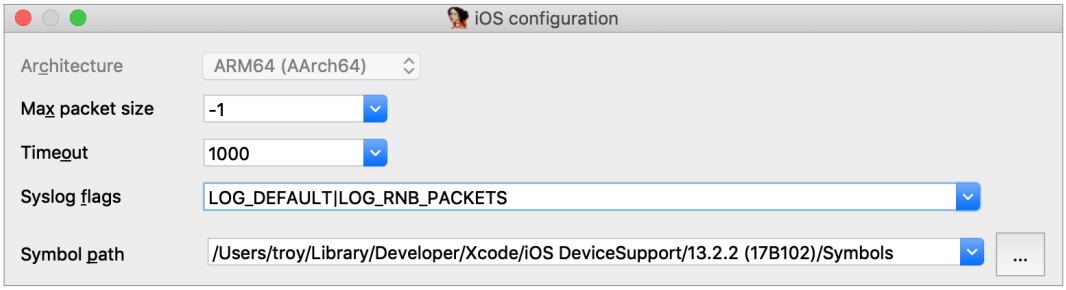
# 7. Troubleshooting

IDA uses the Remote GDB Protocol to communicate with the iOS debugserver. Thus, the best way to diagnose possible issues is to log the packets transmitted between IDA and the server. You can do this by running IDA with the **-z10000** command-line option:

```
$ ida64 -z10000 -L/tmp/ida.log
```

Often times these packets contain messages or error codes that provide clues to the issue.

For more enhanced troubleshooting, you can also enable logging on the server side. Go to **Debugger>Debugger options>Set specific options** and set the **Syslog flags** field:



This will instruct the debugserver to log details about the debugging session to the iOS system log (all valid flags are documented under the **SYSLOG_FLAGS** option in dbg_ios.cfg).

Start collecting the iOS system log with:

```
$ ios_deploy syslog -f /tmp/sys.log
```

Then launch the debugger. Now both the client (/tmp/ida.log) and the server (/tmp/sys.log) will log important events in the debugger session, which will often times reveal the issue.

# 8. Notes

This tutorial replaces the old iOS debugging tutorial, which is available here.
